PLANNING AND DEVELOPMENT

MAY 1983

INTRODUCTION

The population of Minnesota is projected to increase from 4,075,970 in 1980 to 4,370,979 in 1990, a rise of 7.2 percent. This is almost identical to the 7.1 percent rate of growth experienced from 1970 to 1980. Slightly lower increases are projected for the 1990s (5.2%) and 2000s (3.4%). The counties surrounding Minneapolis and St. Paul are expected to have the fastest rates of population growth, while population declines can be anticipated in southern and western Minnesota and on the Iron Range. As the baby boom generation continues to age and elderly people continue to live longer, the median age will rise from 29.2 in 1980 to 39.2 in 2010. The number of older people will increase over the 30-year period. The number of children will increase during the 1990s and then decline.

The fastest rates of population growth during the 1980s are projected in the first and second ring suburban counties surrounding the Twin Cities, especially in Sherburne, Chisago, Wright, Isanti, and Dakota Counties. All of these counties have experienced rapid growth in recent years. After 1990, these areas are projected to continue growing though at a slightly lower rate. The suburban counties will grow faster than other areas of the state throughout the projection period.

In the 1980s, Hennepin County is projected to grow slightly and Ramsey County to decline about 0.1 percent. After 1990, both counties are projected to lose population, though less rapidly than in the past. Hennepin County, which has more area for expansion, will decline more slowly than Ramsey County. Moderate levels of population growth in the 1980s are projected for the lake area counties of north central Minnesota and for a belt of counties directly south of the metropolitan region. These areas will continue to grow, though at lower rates, through the 1990-2000 and 2000-2010 periods.

Population loss is projected in many of the rural counties of southern and western Minnesota. Adverse economic conditions on the Iron Range are also projected to bring about population loss in St. Louis and Lake Counties. The largest population declines during the 1980s will occur in Traverse, Lake, Pipestone, Murray, and Norman Counties. The southern and western counties projected to lose population tend to have considerable outmigration, especially of young adults. Many have lost population in the past.

The continuing impact of the baby boom and baby bust generations is evident throughout the 30-year projection period. The large baby boom cohort will be concentrated in the 30-44 age groups in 1990, the 40-54 year-old groups in 2000, and the 50-64 year-old groups in 2010. In each succeeding decade there will be a large increase in these baby boom age groups. The smaller cohorts born after 1960 during the so-called "baby bust" will also have an effect on age group changes. The number of 15-24 year-olds will be smaller in 1990 than in 1980, and there will be a subsequent decline in the number of 25-34 year-olds in 2000 and the number of 35-44 year-olds by 2010. These changes in the population in various age groups are predictable based on the number of babies born many years earlier.

The number of children under 10 is projected to increase moderately during the 1980s and then decline. The increase will occur even if, as projected, the number of births per woman remains constant and relatively low. This is because so many women from the baby boom era will be in their childbearing years. After 1990, the smaller baby bust cohort will become of childbearing age and there will be a subsequent decline in the number of births.

For most age groups over 75, population increases will occur in every decade. As older people live longer, the number of people in the oldest age

groups will continue to grow rapidly. One exception is the expected decline between 2000 and 2010 in the number of 75-79 year-olds. This is a delayed effect from the Depression of the 1930s, when low birth rates produced a relatively small age cohort. By the year 2000, these Depression-era children will begin moving into their 70s.

The median age of the Minnesota population is projected to increase from 29.2 in 1980 to 32.5 in 1990 and 39.2 in 2010. This increase in median age reflects several factors, including the aging of the baby boom generation, the long-term decline in the number of children, and the increase in the number of older people. The latter two trends in turn reflect continued low fertility rates and a continuation of the trend toward higher survival rates at older ages.

As a result of the decline in the 0-14 year-old population after 1990, the ratio of children to working age adults will decrease substantially from 35.2 per 100 adults age 15-64 in 1980 to 26.7 per 100 in 2010. The number of persons over 65 will grow rapidly in every decade, but this rapid growth will result in only a moderate increase in the aged dependency ratio, from 18.0 in 1980 to 21.0 in 2010. The modest increase in aged dependency can be attributed to the fact that the actual number of people over 65 will remain small relative to other age groups.

After 2010, when the baby boom generation reaches retirement age, the increases in aged dependency will become more marked. Overall, during the 30-year period covered by the projections, the total dependency ratio will go down. The relatively small increases in elderly dependency will be more than offset by the larger decreases in youth dependency.

METHODOLOGY

The population projections presented in this publication were prepared using the cohort-component method. The 1980 Census population by county, age and sex was the starting point. Assumptions were made about the rates of mortality, fertility and migration during each five-year period. The population at the end of each time period reflects the expected number of survivors, births during the period, and additions or subtractions attributable to migration. The projected population then becomes the basis for the next cycle of projection calculations. County projections were controlled to the state totals. Regional projections were derived by adding up the counties in the region.

Mortality Assumptions: Survival rates were assumed to be constant across all counties of the state. The projections assume that survival rates will increase slightly, with the greatest increase at older ages. The 1970s saw a substantial increase in survival rates among older people. The projections assume this trend will continue, although at a more modest rate.

Fertility Assumptions: Fertility rates were assumed to vary according to age but to be constant over time. For the state, the total fertility rate was assumed to be 1.85 births per woman. The counties were classified into one of four fertility categories, ranging from High (2.5 births per woman) to Low (1.7 births per woman). The classification was based on the county's 1979 fertility patterns. The majority of counties fell into one of the two highest fertility categories. Only three counties (Hennepin, Ramsey, and Clay) were in the lowest category.

Migration: Migration rates were assumed to vary by age, sex, and county and also over time. The 1970-1980 net migration rates were used as a starting

point. The general assumption was that migration rates would be reduced by 20 percent in 1980-1990 and by 10 percent in each subsequent decade. This was only a general guideline; additional modifications were made in individual counties based on county-specific trends. For the state as a whole, the projections assumed a return to a slight net outmigration pattern during the 1980s, with decreasing migration in later years. During the 1970s there was a small net inmigration into Minnesota.

COUNTY FERTILITY CLASSIFICATIONS

I. High Fertility Counties

(Total Fertility Rate = 2.53)

Big Stone
Cass
Chippewa
Clearwater
Dodge
Fillmore
Grant
Houston
Kanabec
Lac Qui Parle
